ISSUES

- ExDerivs.R file causes a number of failures in the ORIGINAL numericDeriv.
- Need to verify nlsalt:: version matches all cases of nlspkg:: version

TODOS (mostly from nlsr vignette nlsr-devdoc.Rmd)

- how to insert numerical derivatives when Deriv unable to get result
- approximations for jacfn beyond fwd approximation. How to specify??

- how to force numerical approximations in `nlfb()` in a manner consistent with that used in `optimx::optimr()`, that is, to surround the name of `jacfn` with quotes if it is a numerical approximation, or to provide a logical control to `nlxb()` for this purpose.

Jacobians in `nls()`

This document source is in file **DerivsNLS.Rmd**.

`nls()` needs Jacobians calculated at the current set of trial nonlinear model parameters to set up the Gauss-Newton equations. Unfortunately, `nls()` calls the Jacobian the “gradient,” and uses function `numericDerivs()` to compute them. This document is an attempt to describe different ways to compute the Jacobian for use in `nls()` and related software, and to evaluate the performance of these approaches.

In evaluating performance, we need to know the conditions under which the evaluation was conducted. Thus the computations included in this document, which is built using **Rmarkdown**, are specific to the computer in which the document is processed. We will add tables that give the results for different computing environments at the bottom.

An example problem

We will use the Hobbs weed infestation problem (Nash (1979), page 120).

```
# Data for Hobbs problem
ydat <- c(5.308, 7.24, 9.638, 12.866, 17.069, 23.192, 31.443,
          38.558, 50.156, 62.948, 75.995, 91.972) # for testing
tdat <- seq_along(ydat) # for testing

# A simple starting vector -- must have named parameters for nlxb, nls, wrapnlsr.
start1 <- c(b1=1, b2=1, b3=1)
eunsc <- y ~ b1/(1+b2*exp(-b3*tt))
str(eunsc)

## Class 'formula' language y ~ b1/(1 + b2 * exp(-b3 * tt))
## .. attr(*, ".Environment")=<environment: R_GlobalEnv>

# Can we convert a string form of this "model" to a formula
ceunsc <- " y ~ b1/(1+b2*exp(-b3*tt))"
str(ceunsc)

## chr " y ~ b1/(1+b2*exp(-b3*tt))"

# Will be TRUE if we have made the conversion
print(as.formula(ceunsc)==eunsc)

## [1] TRUE

## LOCAL DATA IN DATA FRAMES
weeddata1 <- data.frame(y=ydat, tt=tdat)

## Put data in an Environment
weedenv <- list2env(weeddata1)
weedenv$b1 <- start1[[1]]
weedenv$b2 <- start1[[2]]
weedenv$b3 <- start1[[3]]
# Display content of the Environment
## Note that may need to do further commands to get everything
ls.str(weedenv)
```

```
## b1 : num 1
## b2 : num 1
## b3 : num 1
## tt : int [1:12] 1 2 3 4 5 6 7 8 9 10 ...
## y : num [1:12] 5.31 7.24 9.64 12.87 17.07 ...

# Generate the residual "call"
rexpr<-call("-",eunsc[[3]], eunsc[[2]])
# Get the residuals
r0<-eval(rexpr, weedenv)
print(r0)

## [1] -4.576941 -6.359203 -8.685426 -11.883986 -16.075693 -22.194473
## [7] -30.443911 -37.558335 -49.156123 -61.948045 -74.995017 -90.972006

cat("Sumsquares at 1,1,1 is ",sum(r0^2),"\n")

## Sumsquares at 1,1,1 is 23520.58

## Another way
ldata<-list2env(as.list(start1),envir=weedenv)
ldata

## <environment: 0x561ab98f2568>
ls.str(ldata)

## b1 : num 1
## b2 : num 1
## b3 : num 1
## tt : int [1:12] 1 2 3 4 5 6 7 8 9 10 ...
## y : num [1:12] 5.31 7.24 9.64 12.87 17.07 ...

eval(rexpr,envir=ldata)

## [1] -4.576941 -6.359203 -8.685426 -11.883986 -16.075693 -22.194473
## [7] -30.443911 -37.558335 -49.156123 -61.948045 -74.995017 -90.972006

## Do we need to get a model frame? How? and How to use it?

## Now ready to try things out.
```

Tools for Jacobians

numericDeriv() original version

numericDeriv is the R function used by nls() to evaluate Jacobians for its Gauss-Newton equations. The R source code is in the file nls.R. It calls a C function numeric_deriv in nls.c.

```
## Seems to work -- BUT note file ExDerivs.R has many "failures"??
theta <- c("b1", "b2", "b3")
ndeunsc<-nlspkg::numericDeriv(rexpr, theta, rho=weedenv)
```

```
## Registered S3 methods overwritten by 'nlspkg':
## method          from
## anova.nls        stats
## coef.nls         stats
## confint.nls      stats
## deviance.nls     stats
```

```

The `dir` parameter allows us to use a backward difference for the derivative. This appears in `nlsModel()` for the case where a parameter is on an upper bound for the case `algorithm="port"`. It does not check for nearness to the bound, and for the lower bound assumes that we are stepping AWAY from the bound in the default direction (`dir=+1`). None of the code addresses the issue where bounds are closer together than the step used for the finite difference, so there are situations where we could crash the code. Nor does the code check if the central difference is specified when near a bound.

- In the case of lower bounds, a central difference can overstep the bound when a parameter is “close” or on the bound.
- In the case of an upper bound, changing the `dir` will not change the derivative expression and steps in both forward and backward directions of the parameter are taken.

Symbolic methods from `nlsr`

The package `nlsr` has a function `model2rjfun()` that converts an expression describing how the residual functions are computed into an R function that computes the residuals at a particular set of parameters and sets the **attribute** “gradient” of the vector of residual values to the Jacobian at the particular set of parameters.

```
# nlsr has function model2rjfun. We can evaluate just the residuals
res0<-model2rjfun(eunsc, start1, data=weeddata1, jacobian=FALSE)
res0(start1)
```

```

```

```
# or the residuals and jacobian
## nlsr::model2rjfun forms a function with gradient (jacobian) attribute
funsc <- model2rjfun(eunsc, start1, data=weeddata1) # from nlsr: creates a function
tmodel2rjfun <- microbenchmark(model2rjfun(eunsc, start1, data=weeddata1))
print(tmodel2rjfun)
```

```
## Unit: microseconds

numDeriv package

The package `numDeriv` includes a function `jacobian()` that acts on a user function `resid()` to produce the Jacobian at a set of parameters by several choices of approximation.

```
# We use the residual function (without gradient attribute) from nlsv
jeunsc<-jacobian(res0, start1)
jeunsc
```

```

Note that the manual pages for `numDeriv` offer many options for the functions in the package. At 2021-5-27

we have yet to explore these.

Comparisons

In the following, we are comparing to `vfunsc`, which is the evaluated residual vector at `start1=c(1,1,1)` with “gradient” attribute (jacobian) included, as developed using package `nlsr`. This is taken as the “correct” result, even though it is possible that the generated order of calculations may introduce inaccuracies in the supposedly analytic derivatives.

`numericDeriv` computes a similar structure (residuals with “gradient” attribute): `ndeunsc`: the forward difference result with default `eps` (1e-07 according to manual) `ndeunsc2`: Central difference with default `eps` `ndeunscx`: Forward difference with smaller `eps`=1e-10 `ndeunscx2`: Central difference with smaller `eps`=1e-10

`jeunsc`: `numDeriv::jacobian()` result with default settings.

Performance results for different computing environments

Here we present tables of the results, preceded by identified descriptions of the machines we used. We use ideas and functions from the document `MachineSummary` to provide a characterization and identity for each machine used.

M21-LM20.1

?? still to be run

?? What machines provide a range of possibilities.

Discussion of derivative computation for nonlinear least squares

In no particular order, we comment on some issues relating to the Jacobian calculations in nonlinear least squares.

Nomenclature

R is not in step with many other areas of numerical computation when labelling different objects in the nonlinear least squares problem. In particular, R uses the term “gradient” when the object of interest is the Jacobian matrix. In that it is useful in performing iterations of the Gauss-Newton or related equations to have the Jacobian associated with the residuals, and the rows of the Jacobian matrix are “gradients” of the respective residuals, we can accept the attribute name “gradient” to select the required information. Moreover, as in package `nlsr` it is very useful to have the Jacobian matrix as an attribute of the residual vector, since the main solver function, in this case `nlsr::nlfb()`, can be called with the same input for the arguments `res` and `jac`. These are the functions required to compute the residual and the Jacobian, and using the same function for both is very convenient, but needs some way to return both the residual vector and Jacobian matrix in a coherent fashion.

Numerical approximation near constraints

As far as we are aware there is no software that implements a fully safeguarded system to compute numerical approximation of the Jacobian (or gradients in general optimization) near constraints. The same statement applies even in the case of the much simpler bounds constraints. Users have a perverse tendency to devise ways to foil our best efforts. For example, they may decide that a good way to specify fixed (i.e., masked) parameters that they do not want to vary during a particular calculation is to specify the lower and upper bound of a parameter at the same value. Later runs may want the parameter constraints relaxed.

In `nlsr::nlxb()`, users may, in fact, specify masked parameters this way. This is a case of “if you can’t beat them, join them,” but it does provide an easily understood way for users to fix values.

More tricky is dealing with constraints that are close together. Note that these may arise from, for example, two linear (planar) constraints that approach at a narrow angle. In the apex where these constraints intersect, we will have tight bounds on parameters. If the constraint is not one that is imposed by the nature of the residual or objective function, for example, a `log()` or square root near zero, then we can generally proceed and allow the derivative approximator to evaluate outside the constraints. Things are decidedly nastier if we do have inadmissible values.

The issue of constraints and the need for a step in parameter values for derivative approximations was one of the motivations for trying to find analytic derivatives in package `nlsr` and the continuing effort to bring them into other R tools.

Appendix 1: Base R `numericDeriv` code

This code is in two files, `nls.R` and `nls.c` and is extracted here.

From nls.R

```
numericDeriv <- function(expr, theta, rho = parent.frame(), dir = 1,
                        eps = .Machine$double.eps ^ (1/if(central) 3 else 2), central = FALSE)
## Note: this expr must be set up as a call to work properly according to JN??
## ?? we set eps conditional on central. But central set AFTER eps. Is this OK.
{
  cat("numericDeriv-Alt\n")
  dir <- rep_len(dir, length(theta))
  stopifnot(is.finite(eps), eps > 0)
  rho1 <- new.env(FALSE, rho, 0)
  if (!is.character(theta) ) {stop("'theta' should be of type character")}
  if (is.null(rho)) {
    stop("use of NULL environment is defunct")
    #      rho <- R_BaseEnv;
  } else {
